

Cyber Security Major Project Introduction : Social Engineering Simulator

The **Social Engineering Awareness Simulator** is a Python-based graphical application developed using the **Tkinter** library. The main goal of this project is to create awareness about common social engineering attacks and train users to respond safely. When the program starts, a main menu is displayed where the user can select different social engineering scenarios such as **Email Phishing**, **Fake Tech Support**, and **Impersonation (Call/Chat)**. Each scenario simulates a real-world cyber attack situation. After selecting a scenario, the user is shown a realistic message or call description along with multiple action choices. The program evaluates the selected action and categorizes it as **High Risk**, **Medium Risk**, or **Low Risk**, providing instant feedback through pop-up messages. The program also maintains an **awareness score** that increases when the user makes safe decisions. At the end, the user can view the total score and the corresponding **awareness level**, helping them understand their cybersecurity awareness.

This project acts as an **interactive training and awareness tool**, educating users about social engineering threats and encouraging secure behavior.
